

THE CORDIC ALGORITHM AND CORDIC ARCHITECTURES

Implementation of Digital Signal Processing

Sabih H. Gerez
University of Twente

OUTLINE

- CORDIC algorithm:
 - Rotation and vectoring modes
- CORDIC architectures
- Applications of CORDIC

WHAT IS CORDIC?

- CORDIC: abbreviation of coordinate rotation digital computer.
- First publication by Volder, 1959.
- A method from the field of *computer arithmetic* allowing for the efficient implementation of a wide range of computations.

VECTOR ROTATIONS (1)

- Consider a sequence of rotations of a vector $(x^{(i)}, y^{(i)})^T$ rotated by α_i to give vector $(x^{(i+1)}, y^{(i+1)})^T$.
- So:
$$\begin{bmatrix} x^{(i+1)} \\ y^{(i+1)} \end{bmatrix} = \begin{bmatrix} \cos(\alpha_i) & -\sin(\alpha_i) \\ \sin(\alpha_i) & \cos(\alpha_i) \end{bmatrix} \begin{bmatrix} x^{(i)} \\ y^{(i)} \end{bmatrix}$$
- After rewrite:
$$\begin{bmatrix} x^{(i+1)} \\ y^{(i+1)} \end{bmatrix} = \cos(\alpha_i) \begin{bmatrix} 1 & -\tan(\alpha_i) \\ \tan(\alpha_i) & 1 \end{bmatrix} \begin{bmatrix} x^{(i)} \\ y^{(i)} \end{bmatrix}$$
- If $\tan(\alpha_i)$ is chosen such that $\tan(\alpha_i) = d_i 2^{-i}$, with $d_i = \pm 1$, then the rotations can be executed without multiplications except for initial factor $\cos(\alpha_i) = \frac{1}{\sqrt{1+2^{-2i}}}$

VECTOR ROTATIONS (2)

- If $\tan(\alpha_i) = d_i 2^{-i}$, this means: $\alpha_i = d_i \arctan(2^{-i})$
- For an arbitrary angle α , $-\frac{\pi}{2} \leq \alpha \leq \frac{\pi}{2}$, the angle can then be decomposed as:

$$\alpha = \sum_{i=0}^n d_i \arctan(2^{-i})$$

- Angles involved:

i	0	1	2	3	4	5	6	7	8
2^{-i}	1	1/2	1/4	1/8	1/16	1/32	1/64	1/128	1/256
$\arctan(2^{-i})$ [deg]	45.0	26.6	14.0	7.1	3.6	1.8	0.9	0.4	0.2

VECTOR ROTATION EXAMPLE

- The 8 subsequent rotations for a rotation of 15 degrees are:

i	0	1	2	3	4	5	6	7	8
2^{-i}	1	1/2	1/4	1/8	1/16	1/32	1/64	1/128	1/256
$\arctan(2^{-i})$	45.0	26.6	14.0	7.1	3.6	1.8	0.9	0.4	0.2
d_i	1	-1	-1	1	1	-1	1	1	1
$\sum \alpha_i$	45.0	18.4	4.4	11.5	15.1	13.3	14.2	14.7	14.9

- The arctangent values can be precomputed and stored in a look-up table (LUT), say $L(i)$.
- The d_i depend on the required rotation angle.

ANGLE ACCUMULATION

- Keep track of total rotation angle in an *angle accumulator*:

$$z^{(i+1)} = z^{(i)} - d_i L(i)$$

- The angle accumulator can be used to determine d_i :
 - Initialize $z^{(0)} = \alpha$.
 - Factor d_{i+1} becomes 1 when $z^{(i)} \geq 0$ and -1 otherwise.

CORDIC EQUATIONS SUMMARY

- Original equations were:

$$\begin{bmatrix} x^{(i+1)} \\ y^{(i+1)} \end{bmatrix} = \cos(\alpha_i) \begin{bmatrix} 1 & -\tan(\alpha_i) \\ \tan(\alpha_i) & 1 \end{bmatrix} \begin{bmatrix} x^{(i)} \\ y^{(i)} \end{bmatrix}$$

- Making use of the special values for the tangent, leaving out the multiplication by the cosine and combining with angle accumulation, one gets:

$$\begin{aligned} x^{(i+1)} &= x^{(i)} - d_i 2^{-i} y^{(i)} \\ y^{(i+1)} &= d_i 2^{-i} x^{(i)} + y^{(i)} \\ z^{(i+1)} &= z^{(i)} - d_i L(i) \end{aligned}$$

ROTATION-MODE CORDIC

- Goal is to rotate vector by angle α .

- Final result:

$$\begin{aligned} x^{(n)} &= K(x \cos(\alpha) - y \sin(\alpha)) \\ y^{(n)} &= K(x \sin(\alpha) + y \cos(\alpha)) \\ z^{(n)} &= 0 \end{aligned}$$

- Initialization:

$$\begin{aligned} x^{(0)} &= x \\ y^{(0)} &= y \\ z^{(0)} &= \alpha \end{aligned}$$

- Where:

$$K = \prod_{i=1}^n \sqrt{1 + 2^{-2i}}$$

- K converges to 1.647.
- Conclusion: the result vector is rotated but scaled version of original vector.

VECTORIZING-MODE CORDIC

- Determine d_i by an alternative rule: $d_i = -1$ when $y^{(i)} > 0$ and $d_i = +1$ when $y^{(i)} \leq 0$.

- Final result:

$$\begin{aligned} x^{(n)} &= K \sqrt{x^2 + y^2} \\ y^{(n)} &= 0 \\ z^{(n)} &= \arctan\left(\frac{y}{x}\right) \end{aligned}$$

- Initialization:

$$\begin{aligned} x^{(0)} &= x \\ y^{(0)} &= y \\ z^{(0)} &= 0 \end{aligned}$$

- This means that the initial vector has been rotated (and scaled) onto the X-axis, while the angle with the X-axis has been computed as well.

BASIC APPLICATIONS OF CORDIC

- Arctangent, vector-magnitude* calculation and *rectangular-to-polar conversion*: direct result of vectoring-mode CORDIC.
- Polar-to-rectangular conversion*, i.e. from (r, θ) to (x, y) :
 - Set $x^{(0)} = r$, $y^{(0)} = 0$, and $z^{(0)} = \theta$ in rotation mode.
 - Result will be $x = x^{(n)} = Kr \cos(\theta)$, $y = y^{(n)} = Kr \sin(\theta)$.
 - Correction for scaling by K may be necessary (does not require a full-fledged multiplier as K is constant).
- Sine or cosine* calculation:
 - See above, set $x^{(0)} = 1/K$. Then $x^{(n)} = \cos(\theta)$ and $y^{(n)} = \sin(\theta)$.

ARCHITECTURE ITERATIVE CORDIC

$$\begin{aligned}x^{(i+1)} &= x^{(i)} - d_i 2^{-i} y^{(i)} \\y^{(i+1)} &= d_i 2^{-i} x^{(i)} + y^{(i)} \\z^{(i+1)} &= z^{(i)} - d_i L(i)\end{aligned}$$

Controller should take care of initializations, add/subtract decisions, number of iterations, etc.

UNROLLED ARCHITECTURE

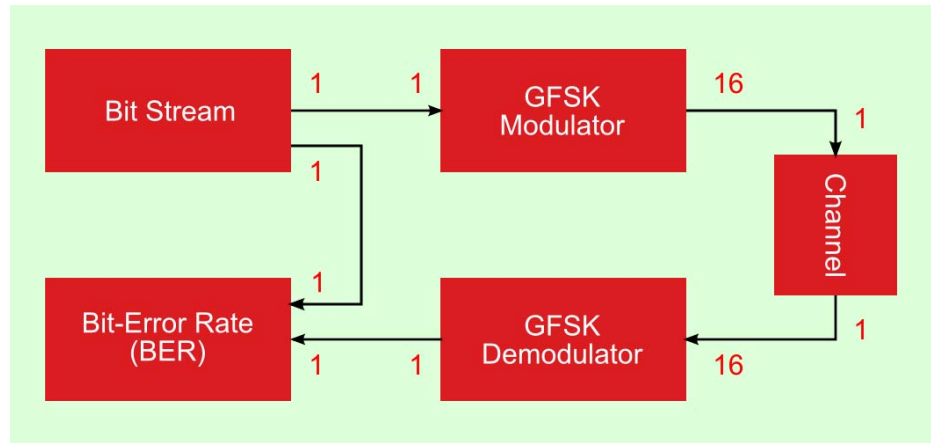

- The iterative architecture requires one clock cycle per iteration.
- It requires a *barrel shifter* to shift operand over a variable number of positions.
- One can also *unroll* the architecture to perform all operations in a single clock cycle:
 - Amounts to instantiate new hardware for each iteration.
 - Possibly adding *pipelining* if the *critical path* becomes too long.
 - The barrel shifter is no longer necessary: each stage in the hardware has a fixed shift which costs just wires.
 - One could also unroll the architecture partially.

DESIGN EXAMPLE: GFSK RECEIVER

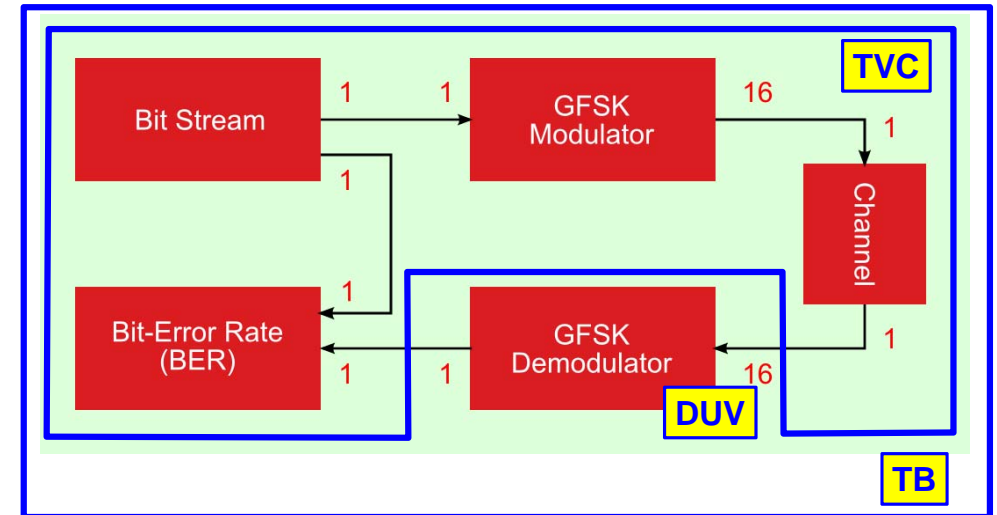

- What is GFSK?
 - *Gaussian frequency shift keying*
 - Method for digital transmission based on frequency modulation (FM).
 - To transmit a **1** carrier frequency is slightly increased and to transmit a **0** the frequency is slightly decreased (or vice versa).
 - The transition steps are smoothed by a Gaussian filter.
 - Found in many standards: Bluetooth, DECT, Wavenis, ...
 - Proposed version uses parameters not related to any standard.

GFSK RECEIVER DESIGN APPROACH

- Model entire system: transmitter, receiver, and a channel adding noise (AWGN).
- Leave out analog circuitry for upconversion to RF and downconversion back to IF.
- Use **IT++** to set up testbench.
- The testbench computes bit error rates (BERs) for different signal-to-noise ratios (SNRs).
- Goal is to preserve BER performance when designing hardware.

Modulated signal has 16 samples per transmitted bit.

DUV = design under verification

TVC = test-vector controller; TB = testbench

IMPLEMENTATION ASPECTS

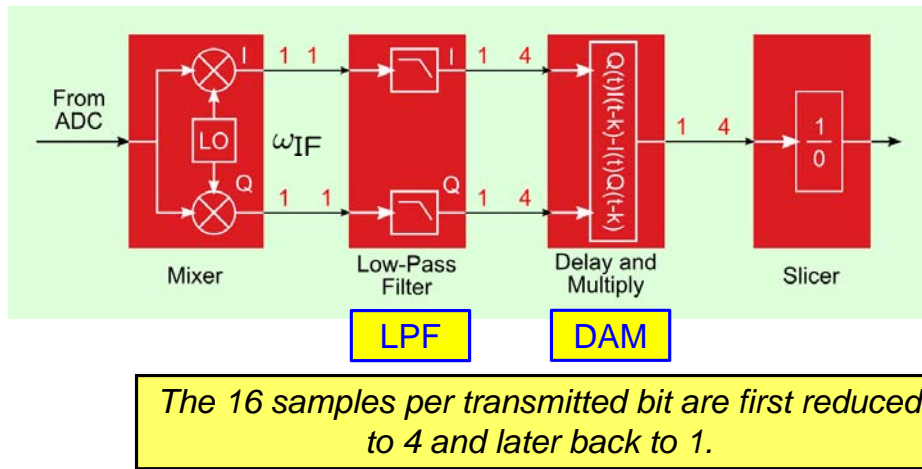

- Projects focus on designing in Arx.
- Testbenches for generated C++ and VHDL will be provided.
- As C++ and VHDL behave exactly the same, most simulations will be done in C++ (simulation speed in e.g. BER simulations is important).
- C++ testbenches make use of **IT++**, an open-source library for telecom/signal processing:
 - <http://itpp.sourceforge.net>
 - It provides Matlab-style programming in C++, so vectors, matrices, etc. and lots of powerful functions to manipulate them.

GFSK: MODULATION IN FORMULAE

- The modulated signal: $s(t) = A \cos(\omega_{IF}t + \phi(t))$
- where:
 - A is the constant amplitude
 - ω_{IF} is the *intermediate frequency* (acts as carrier frequency)
 - $\phi(t)$ is the phase deviation, derived from the bit stream
- The phase deviation:

$$\phi(t) = h\pi \int_{-\infty}^t \sum_i a_i g(\tau - iT) d\tau$$
- where:
 - h is the modulation index
 - $g(t)$ is a Gaussian-filtered square wave
 - a_i is 1 for a transmitted **1** and -1 for a transmitted **0**.

DEMODULATOR BLOCK DIAGRAM

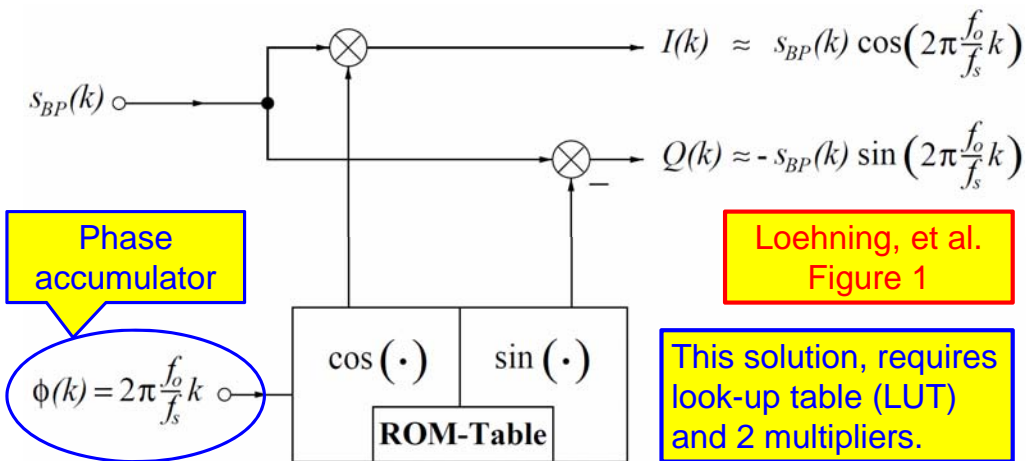

CORDIC FOR DOWNCONVERSION (1)

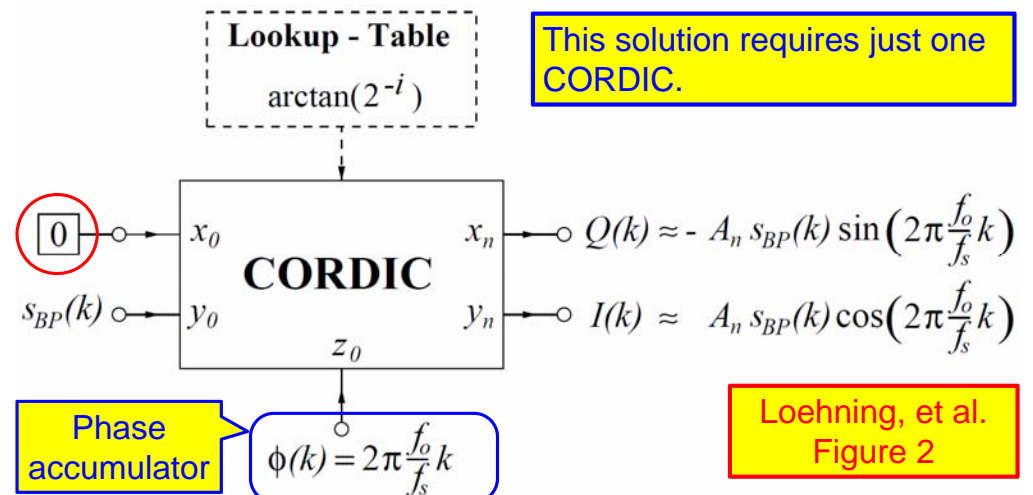

- *Digital downconversion* is a common operation in digital radio receivers. It is used to shift the carrier frequency of a radio signal (e.g. from IF to baseband) or correct for frequency offset.
- This is done by multiplying an input signal by a sine and cosine of some frequency. Think of the GFSK demodulator.

CORDIC FOR DOWNCONVERSION (2)

CORDIC FOR DOWNCONVERSION (3)

CORDIC FOR DOWNCONVERSION (4)

IMAGE REJECTION MIXER:
"complex" input with in-phase (I) and quadrature (Q) component.
CORDIC replaces 4 multipliers!
