

## FIXED-POINT DESIGN

- Central issue: how to perform a desired computation with as few bits per operand as possible
- Some material based on:
  - Bouganis, C.S. and G.A. Constantinides, "Synthesis of DSP Algorithms from Infinite Precision Specifications", In: P. Coussy and A. Morawiec (Eds.), High-Level Synthesis, From Algorithm to Digital Circuit, Springer, pp. 197-214, (2008).
  - NN, *SystemC Version 2.0 User's Guide, Update for SystemC 2.0.1*, (2002).
- Thanks to Jeroen de Zoeten, for some material reused from his M.Sc. graduation presentation (2004).

## TOPICS

- Fixed-point data types
- SystemC
- Peak-value estimation
- Word-length optimization

## FIXED-POINT DATA TYPES

- A specific interpretation of a logic vector
  - Binary point
  - Integer and fractional part:  $iw1$  and  $fw1$  (integer and fractional word length)
  - Signed or unsigned

## EXAMPLES OF FIXED-POINT NUMBERS

- Example pattern: 1101
  - With  $iw1 = 2$  and unsigned  $\rightarrow 13/4$
  - With  $iw1 = 2$  and signed  $\rightarrow -3/4$
  - With  $iw1 = 6$  and unsigned  $\rightarrow 52$
  - With  $iw1 = 6$  and signed  $\rightarrow -12$
  - With  $iw1 = -1$  and unsigned  $\rightarrow 13/32$
  - With  $iw1 = -1$  and signed  $\rightarrow -3/32$

## FIXED-POINT ADDITION/SUBTRACTION

- Integer adder can be used after:
  - Alignment of binary point
  - Sign extension

© Sabih H. Gerez, University of Twente, The Netherlands

## FIXED-POINT MULTIPLICATION

- Integer multiplier can directly be used.
- One only needs to figure out the location of the binary point.

© Sabih H. Gerez, University of Twente, The Netherlands

## QUANTIZATION: TRUNCATION

- If the target provides less accuracy than the value to assign:
  - Truncation* → no hardware
  - What happens to the signal in EE terms?

© Sabih H. Gerez, University of Twente, The Netherlands

## QUANTIZATION: ROUNDING

- If the target provides less accuracy than the value to assign:
  - Rounding* (various modes) → extra hardware

© Sabih H. Gerez, University of Twente, The Netherlands

## OVERFLOW: WRAP AROUND

- If the value to assign is outside the range of target:
  - Wrap around* → no hardware

© Sabih H. Gerez, University of Twente, The Netherlands

## OVERFLOW: SATURATION

- If the value to assign is outside the range of target:
  - Saturation* (various modes) → extra hardware

© Sabih H. Gerez, University of Twente, The Netherlands

## SystemC

- Open source standard for system-level modeling, based on C++ class libraries and a simulation kernel.
- Provides modeling from system level down to (mainly) register-transfer level (RTL).
- For more details, see the *Accellera* web site (non-profit organization for system-level design):

<http://www.accellera.org/>

© Sabih H. Gerez, University of Twente, The Netherlands

## SystemC FIXED-POINT DATA TYPES

- Declaration (signed and unsigned version):
 

```
sc_fixed<wl, iwl, q_mode, o_mode, n_bits> x;
sc_ufixed<wl, iwl, q_mode, o_mode, n_bits> x;
```
- wl**: word length,  $iwl + fwl$
- iwl**: integer word length
- q\_mode**: (optional) quantization mode, default is truncation
- o\_mode**: (optional) overflow mode, default is wrap around
- n\_bits**: (optional) number of bits for overflow (**n\_bits** are saturated, the others are wrapped around)
- sc\_fix/sc\_ufix** data types can be resized at run time

© Sabih H. Gerez, University of Twente, The Netherlands

## SystemC FIXED-POINT CODE EXAMPLE

```

sc_fixed<6, 2> a;
sc_fixed<6, 4> b;
sc_fixed<3, 2, SC_RND, SC_SAT> c;

c = a + b;

```

- Implementation:
  - Calculate sum at full precision
  - Perform quantization processing
  - Perform overflow processing

## THE FIXED-POINT DESIGN PROBLEM (1)

- Mathematical descriptions of DSP algorithms often assume infinite precision in the signal representation.
- The closest approximation of infinite precision in computers is the *floating-point* number representation.
- Floating-point hardware is expensive and is avoided if possible.
- Implementations therefore use fixed-point hardware.
- Problem: *which fixed-point formats should be used to obtain the cheapest implementation of the original algorithm?*

## THE FIXED-POINT DESIGN PROBLEM (2)

- One should look at:
  - The dynamic range: avoid *overflow* and therefore know *peak values*.
  - The accuracy: *quantization* levels.

## BOUGANIS FIXED-POINT FORMAT

*Considers signed numbers only; sign bit is not counted in size.*

## PEAK-VALUE ESTIMATION

- Related to the fact that signal magnitude may grow due to addition or multiplication
- In a stable system, the signal cannot grow indefinitely
- Question is: what is the maximal value encountered for each signal in the system?
- Issue is not directly related to accuracy, the number of bits used for each signal.

## PEAK-VALUE ESTIMATION METHODS

- Analytic:
  - examine transfer functions
- Data-range propagation:
  - Interval analysis
  - Compute result interval from input intervals
  - Tends to overestimate requirements
- Simulation-driven analysis:
  - Monitor values produced during a representative simulation and record extremes
  - Use a safety factor > 1

## ANALYTIC PEAK-VALUE ESTIMATION

- Consider an FIR filter:

$$y[n] = \sum_{k=0}^N h[k] \cdot x[n - k]$$

- Then, an upper bound for the output value is found by:

$$y_{\text{peak}} = x_{\text{peak}} \sum_{k=0}^N |h[k]|$$

- For recursive filters, a similar approach can be followed, starting from a state-space representation.

## INTERVAL ANALYSIS (1)

- Represent each value  $x$  as an interval:  $\tilde{x} = [x^-, x^+]$
- For each arithmetic operation, one can calculate the result interval from the operand intervals. For example:

$$\begin{aligned} \tilde{x} + \tilde{y} &= [x^- + y^-, x^+ + y^+] \\ \tilde{x}\tilde{y} &= [\min(x^-y^-, x^-y^+, x^+y^-, x^+y^+), \\ &\quad \max(x^-y^-, x^-y^+, x^+y^-, x^+y^+)] \end{aligned}$$

## INTERVAL ANALYSIS (2)

## WORD-LENGTH PROPAGATION

Type	Propagation rules
GAIN	For input $(n_a, p_a)$ and coefficient $(n_b, p_b)$ : $p_j = p_a + p_b$ $n_j^q = n_a + n_b$
ADD	For inputs $(n_a, p_a)$ and $(n_b, p_b)$ : $p_j = \max(p_a, p_b) + 1$ $n_j^q = \max(n_a, n_b + p_a - p_b) - \min(0, p_a - p_b) + 1$ (for $n_a > p_a - p_b$ or $n_b > p_b - p_a$ )
DELAY or FORK	For input $(n_a, p_a)$ : $p_j = p_a$ $n_j^q = n_a$

## QUANTIZATION: NOISE MODELING (1)

- Suppose signal with fixed-point format  $(n, 0)$  is multiplied with another signal with fixed-point format  $(n, 0)$  and the result is truncated to  $n$  bits.
- Error ranges from 0 to  $2^{-2n} - 2^{-n} \approx -2^{-n}$
- Uniform distribution of error:  $p(e) = 2^n, e \in [-2^{-n}, 0]$
- Consider multiplication; is the error really uniformly distributed?

## NOISE MODELING (2)

- Average error is:  $-2^{-(n+1)}$
- Variance:

$$\sigma^2 = \int_{-2^{-n}}^0 2^n [e + 2^{-(n+1)}]^2 de = \frac{1}{12} 2^{-2n}$$

## NOISE PROPAGATION

- In linear time-invariant (LTI) systems, one can analytically calculate the effect of quantization in input or intermediate nodes to noise on the output.
- In case of non-linear systems, one could linearize the system by means of Taylor expansion (a similar approach as a small-signal model used in electronics).
- Noise propagation methods have the advantage of reduced computational complexity with respect to a simulations-only approach.

## FIXED-POINT OPTIMIZATION PROBLEM

- Define a *performance measure*. Examples:
  - SNR at the output of a filter
  - Bit-error rate in a communication system
- Define a *cost measure*, such as the *area* of the circuit.
- Goal is to satisfy a performance requirement at minimal cost by optimally choosing a fixed-point format for each signal in the system.
- The most practical approach is to start with a floating-point model and gradually replace the data types by fixed-point types while monitoring performance by simulations.

## SCHEDULING, ETC.

- Sharing of resources across multiple clock cycles puts additional constraints on the fixed-point format of signals.

## NON-MONOTONIC BEHAVIOR

- One would expect that larger word lengths always improve the performance measure.
- It is possible, however, to construct systems where performance is non-monotonic, see:
  - Constantinides, G.A., P.Y.K. Cheung and W. Luk, *Synthesis and Optimization of DSP Algorithms*, Kluwer Academic Publishers, Boston, (2004).
- Such systems have *forks* that use different fixed-point formats at each end and reconverge.
